

ABSTRACT OF THE DISCLOSURE

The present invention reduces the scale of circuitry and shortens the code phase detection time needed to achieve initial synchronization. In a correlator for calculating 5 correlation between a received spreading code contained in a received spread-spectrum signal and a reference spreading code, a combined code generator is included. The combined code generator outputs a combined spreading code by weighting and combining a plurality of phase-shifted reference spreading codes $A_1 - A_M$. Further, an arithmetic circuit calculates correlation between the received spreading code and the 10 plurality of phase-shifted reference spreading codes simultaneously. A phase detection circuit detects the phase difference between the received spreading code and a reference coding code, namely the phase of the received spreading code from the results of the arithmetic operation.
